Are Your Passwords Safe: Energy-Efficient Bcrypt Cracking with Low-Cost Parallel Hardware August 19, 2014

Motivation

- Bcrypt is:
 - Slow
 - Sequential
 - Designed to be resistant to brute force attacks and to remain secure despite hardware improvements
- You could almost think why even bother optimizing

But

Are Your Passwords Safe: Energy-Efficient Bcrypt Cracking with Low-Cost Parallel Hardware

August 19, 2014

Outline

Bcrypt

Ø Implementations

- Parallella/Epiphany
- ZedBoard and ZC706
- **8** Experimental Results
- 4 Future work

6 Takeaways

Are Your Passwords Safe: Energy-Efficient Bcrypt Cracking with Low-Cost Parallel Hardware August 19, 2014 4 / 21

-

Bcrypt

Bcrypt

- Based on Blowfish block cipher
- Expensive key setup
- User defined cost setting
- Pseudorandom memory accesses

Architecture Epiphany

- 16/64 32-bit RISC cores operating at up to 1 GHz/800 MHz
- Energy-efficient 2 W maximum chip power consumption
- 32 KB of local memory per core
- FPU can be switched to integer mode

Implementation Epiphany

- John the Ripper prepares data on ARM cores
- Bcrypt hashes computed on Epiphany
- Optimized in assembly
- Each Epiphany core computes two bcrypt hashes
- Computation overlapped to exploit dual-issue architecture
 - Integer ALU
 - FPU in integer mode

Architecture Zynq 7020 and Zynq 7045

- Heterogeneous device
- Dual ARM Cortex-A9 MPCore
- Advanced low power 28nm programmable logic
- Zynq 7045 \sim 4 times bigger than Zynq 7020
- AXI buses used for CPU-FPGA communication

Implementation

Zynq 7020 and Zynq 7045

- John the Ripper prepares data on ARM cores
- Bcrypt instances compute hash(es)

9 / 21

Implementation Number of concurrent instances

- Number of concurrent instances limited by available BRAM
- Overlapping multiple bcrypt instances in one module
 - ▶ 56, 70 or 112 instances on Zynq 7020 with 140 BRAMs

or many more on Zynq 7045 with 545 BRAMs

- Large communication overhead for low bcrypt cost setting
- Hardware defects of boards limit optimizations

Epiphany vs x86

Theoretical Peak Performance Analysis Theory

$$c/s = \frac{N_{ports} * f}{(2^{cost} * 1024 + 585) * N_{reads} * 16}$$

- *N_{ports}* number of available read ports to local memory or L1 cache
- *N_{reads}* number of reads per Blowfish round
- 2^{cost} * 1024 + 585 number of Blowfish block encryptions in bcrypt hash computation
- f (in Hz) clock rate

bcrypt(cost, salt, pwd)
1: $state \leftarrow InitState()$
2: $state \leftarrow ExpandKey(state, salt, key)$
3: repeat(2 ^{cost})
4: $state \leftarrow ExpandKey(state, 0, salt)$
5: $state \leftarrow ExpandKey(state, 0, key)$
6: $ctext \leftarrow$ "OrpheanBeholderScryDoubt"
7: repeat(64)
8: $ctext \leftarrow EncryptECB(state, ctext)$
9: return Concatenate(cost, salt, ctext)

Related work

- F.Wiemer, R. Zimmermann. Speed and Area-Optimized Password Search of bcrypt on FPGAs
 - bcrypt running on ZedBoard at 80 MHz
 - 40 parallel instances
 - ▶ 5208 c/s at cost 5, 41.6 c/s at cost 12
- Yuri Gonzaga, Google Summer of Code 2011

Future work

- Parallella/Epiphany
 - Using both Epiphany and Zynq 7020 at once
 - Possible to integrate up to 64 chips on a single board
 - Scalability of current implementation is promising
 - \blacktriangleright 64 * 64 = 4096 cores with theoretical performance of 300000 c/s
- FPGA
 - Zynq 7020 and 7045 optimizations
 - Improve clock rate
 - $\circ~$ Reduce communication overhead
 - Targeting bigger FPGAs
 - Targeting multi-FPGA boards

Takeaways

- Many-core low power RISC platforms and FPGAs are capable of exploiting bcrypt peculiarities to achieve comparable performance and higher energy-efficiency
- Higher energy-efficiency enables higher density
 - More chips per board, more boards per system
- It doesn't take ASICs to improve bcrypt cracking energy-efficiency by a factor of 45+
 - Although ASICs would do better yet
